H3ABioNet PostGWAS Course 2023
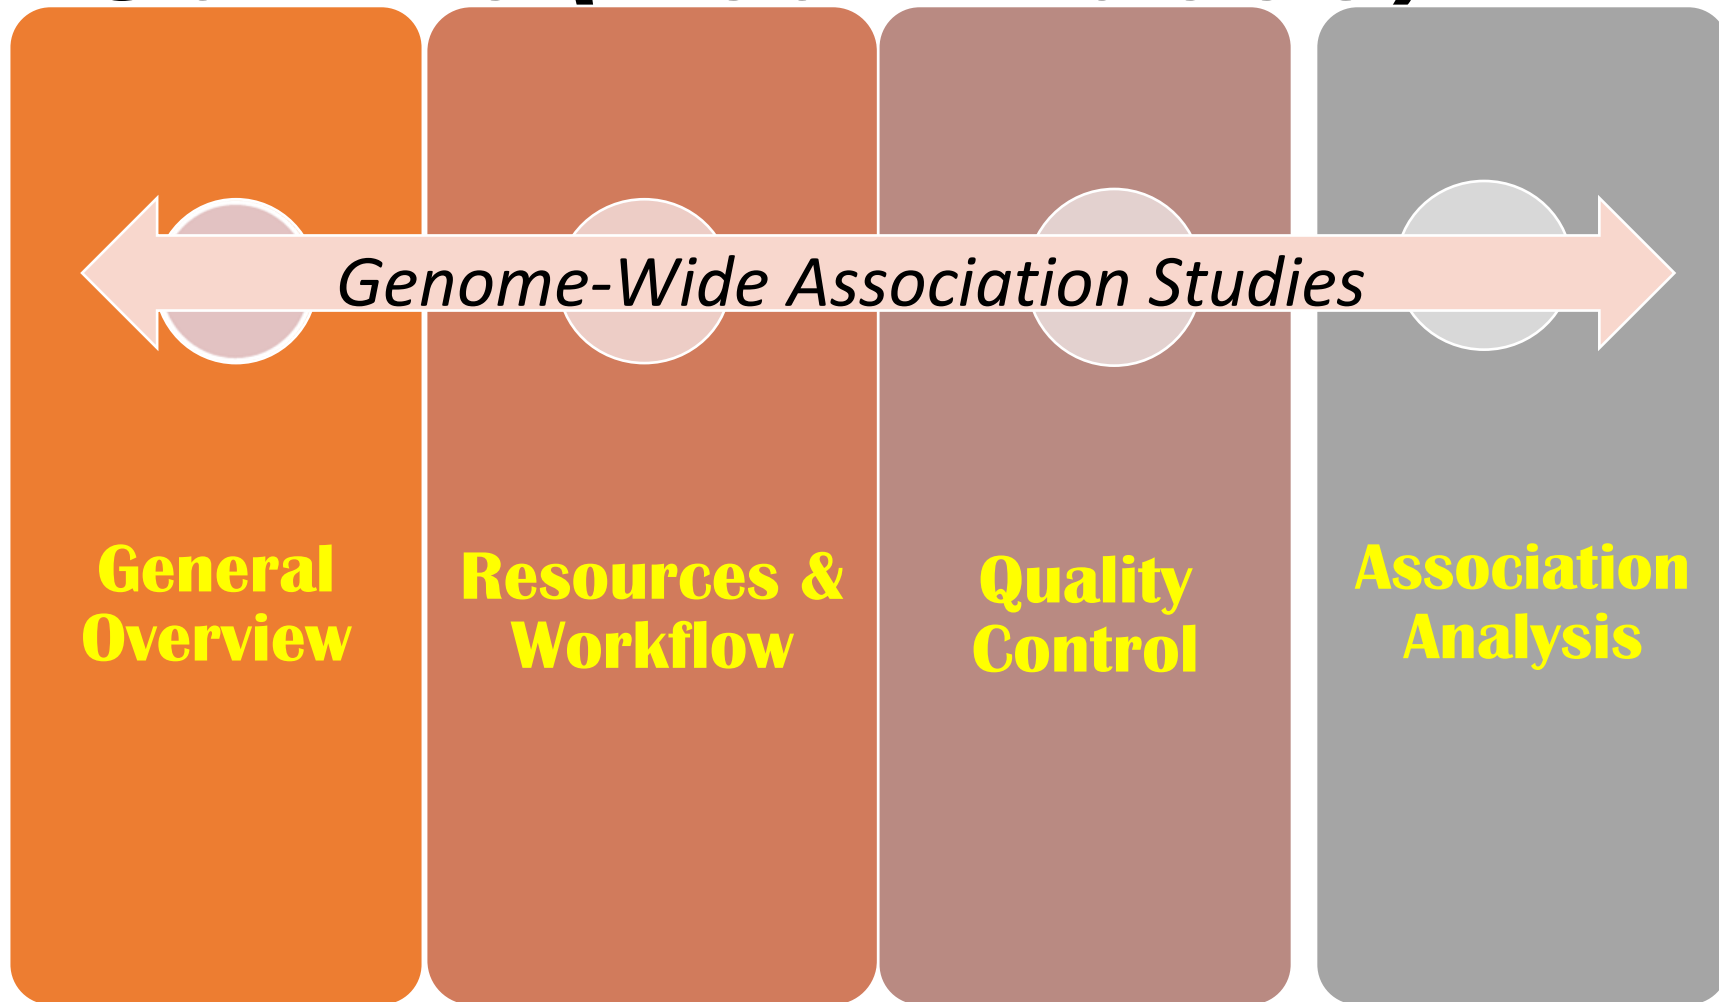

Genome-Wide Association Study (GWAS): Overview

Segun Fatumo *PhD*

Associate Professor, Department of Non-Communicable Disease Epidemiology, LSHTM, UK
Group Leader, The African Computational Genomics Group, MRC/UVRI and LSHTM, Uganda

Outline (Four Videos)

Genome-Wide Association Studies

General Overview

Resources & Workflow

Quality Control

**Association Analysis**

Aims of the Session

- To explain the contribution of genetic variation in disease and phenotype

- To provide an overview of the design of genome-wide association studies (GWAS)

- To narrate the emergence of GWAS

Intended Learning Outcomes

By the end of the session, students will be able to

- Describe roles of between gene in diseases

- Discuss the concept of genome-wide association study (GWAS)

- Explain the history of GWAS till date

Genotype-Phenotype Associations

Phenotype   **Gene**

-
- **Phenotype**
  - Disease   (Diabetes, chronic kidney disease, covid-19, etc)
  - Trait   (Height, Weight, BMI, etc)
  - Lifestyle   (Smoking, Alcohol, Diet, etc)
 - others   (Annual Salary, intelligence, etc)

Quiz

1. Can you think of some phenotype of interest to you ?

2. Do you think genes play a role in your phenotypes of interest ?

3. Apart from genetic variation, what other factors contribute to your phenotype of interest ?
Genetic variations cause inherited diseases
Genetic Diseases

Complex Diseases

Environmental Diseases

- **Cystic fibrosis**

- **Down syndrome**

- **Sickle cell disease**

- **Turner syndrome**

- **Alzheimer disease**

- **Cardiovascular Disease**

- **Diabetes (type 2)**

- **Parkinson Disease**

- **Influenza**

- **Hepatitis**

- **Measles**

- Environment   - Genes

GWAS

- The Genome-wide association studies (GWAS) is an experimental design used to **identify associations between genetic variants and traits** in samples from populations.

- The next big advancement in the field of genetics after the Human Genome Project was GWAS.

COMMENT

Check for updates

15 years of genome-wide association studies and no signs of slowing down

Ruth J. F. Loos [1,2]

Over the past 15 years, genome-wide association studies (GWASs) have generated a wealth of new information. Larger samples sizes, refined phenotypes and higher-resolution genome-screens will continue to drive gene discovery in years ahead. Meanwhile, GWAS loci are increasingly translated into new biology and opportunities for clinical care.

Loos, R. J. (2020). 15 years of genome-wide association studies and no signs of slowing down. *Nature Communications*, *11*(1), 1-3.

H3ABioNet
Pan African Bioinformatics Network for H3Africa

Why was GWAS not possible 20 years ago ?

- Human Genome Project costs **$2.7 billion** over a decade.

- First, need a method able to genotype thousands/millions of polymorphisms at once– chip-based microarray technology

- Second, need to know where are the common polymorphisms– HapMap project

- Third, need HUGE cohorts of people to find subtle allele frequency differences

Genotyping Systems

Affymetrix (Thermo Fisher Scientific)
Illumina

A significant proportion of common SNPs can be captured

Haplotype Map of the Human Genome

The HapMap is a **catalog of common genetic variants that occur in human beings with geographically diverse ancestry**.

90 Yoruba individuals (30 trios) from Ibadan, Nigeria (YRI)
90 individuals (30 trios) of European descent from Utah (CEU)
45 Han Chinese individuals from Beijing (CHB)
45 Japanese individuals from Tokyo (JPT)

First GWASs (2005 - 2007)

- Age related macular degeneration was the first positively associated disease which was found in 2005, using 96 Caucasian individuals with this disease and only 50 without.

- 100,000 SNP's were used in this study.

- 2 associations (1 false)
Results of famous WTCCC study of seven diseases on 14,000 cases and 3,000 controls (Nature, 2007)
- 500,568 SNPs Affymetrix GeneChip 500K Array Set
- Total found: 24 associations at level $5*10^{-7}$

Normal — The Macula is clear and intact in the normal human retina

Macular Degeneration — The Macula is distorted and bleeding which is common in macular degeneration

# GWAS till date

Despite repeated calls and warning, genomics eurocentric bias is on the rise
2016
- Europeans: 81%
- Africans: 3%

2019
- Europeans: 78.39%
- Africans: 2.03%

2022
- Europeans: 86%
- Africans: 1.1%
Popejoy, A., Fullerton, S. 2016 *Nature* **538**, 161–164

Sirugo *et al.,* 2019. *Cell, 177*(1), 26-31.

Fatumo *et al.,* 2022 *Nature Medicine, 28*(2), 243-250.

The 1.1% Africans in Genomic studies are mainly African Americans

- *Studying a small number African diaspora populations (African American and Black participants in the UK and Europe) and grouping all participants into <u>a broad category of African ancestry will continue to promote genomic imbalance</u>, <u>widen health disparities, and fail to capture the genetic diversity in Africa.</u>*

Scientists need to WALK the TALK

UK Biobank (n=~500,000)

~38,000 individuals with non-European ancestry

92.7% of publications excluded non-EUR samples

Zhao et al 2021 ; medRxiv 2021.11.19.21266436

- Nearly 9 of every 10 genomics studies (86.3%) were conducted with people of European ancestry, despite the group constituting only 16 percent of the world's population.

- Despite the scientific rationale for inclusion of African populations, only 1.1% of African participants in GWAS catalog are mainly African Americans which are not truly representative of the genetic diversity in Africa.

In Brief

Genome-wide data from Ugandans reveal insights into their ancestry, trait heritability, and loci associated with metabolic parameters, thereby providing a diverse resource for the study of African population genetics.

A1, effect allele; A2, non-effect allele; neut_count, neutrophil count; NA, not applicable; p_assoc, p value from RE2 (Han-Eskin) METASOFT meta-analysis across cohorts (where relevant); p het, p value for Cochran's Q heterogeneity statistic. See Tables S6.2–S6.8 for all results, and Figures 6 and S10 for locusview plots.

[a] These associations were found to be driven by the $\alpha^{-3.7}$ thalassemia deletion on further sensitivity analyses.

Summary

- GWAS involve testing genetic variants across the genomes of many individuals to identify genotype–phenotype associations.

- Since the first GWAS in 2005, nearly 250K associations of genome-wide significance ($P < 5 \times 10^{-8}$) have been reported between genetic variants and common diseases and traits.

- However, GWAS have mostly focused on individuals of European descent. There is a need for diversity.
